Introduction. Despite static analysis, Abaqus also offers several methods to study dynamic problems. In essence, in a dynamic problem the effect of inertia should be considered in the analysis and the objective is to study the temporal response of the system under specific conditions (for example to simulate the deformation of sheet metals in the metal punching process, to study dynamic loads transmitted to an electronic device when it is dropped on a hard surface, or to study the transient ...

General linear or nonlinear dynamic analysis in Abaqus/Standard uses implicit time integration to calculate the transient dynamic response of a system. See Implicit dynamic analysis using direct integration, or Implicit dynamic analysis, for details on implicit dynamic analysis. This task shows you how to: Create or edit a dynamic, implicit procedure

### Configuring a dynamic, implicit procedure

Dynamic stress/displacement analysis. This option is used to provide direct integration of a dynamic stress/displacement response in Abaqus/Standard analyses and is generally used for nonlinear cases. It is used to perform a dynamic stress/displacement analysis using explicit integration in Abaqus/Explicit.The analysis in both Abaqus/Standard and Abaqus/Explicit can also be adiabatic.

In ABAQUS/Explicit a small amount of numerical damping is introduced by default in the form of bulk viscosity to control high frequency oscillations; see "Explicit dynamic analysis," Section 6.3.3, for more information about this other form of damping.

Steady-state dynamic analysis provides the steady-state amplitude and phase of the response of a system due to harmonic excitation at a given frequency. Usually such analysis is done as a frequency sweep by applying the loading at a series of different frequencies and recording the response; in ABAQUS/Standard the steady-state dynamic analysis procedure is used to conduct the frequency sweep.
